

JAVAGURU INTRODUCTION TO JAVA

---

# LESSON 7

# CONCEPTS OF OBJECT ORIENTED PROGRAMMING

# FOUR PILLARS OF OBJECT ORIENTED PROGRAMMING

## ENCAPSULATION OVERVIEW

- ▶ Binding of data and behaviour together in a **single** unit
- ▶ Data is **not accessed directly**, but through the methods present inside class
- ▶ Makes the concept of **data hiding** possible

## ACCESS MODIFIERS OVERVIEW

- ▶ Specifies which classes can **access** a given **class** and its **fields**, **constructors** and **methods**
- ▶ **Classes**, **fields**, **constructors** and **methods** can have one of four different **access** modifiers:
  - ▶ private
  - ▶ default (package private)
  - ▶ protected
  - ▶ public

## PRIVATE ACCESS MODIFIER: SUMMARY

- ▶ When element is declared as **private**, then only code **inside the same class** can **access** it
- ▶ **Declarable** code elements:
  - ▶ Fields (variables)
  - ▶ Methods
  - ▶ Constructors
- ▶ **Restricted** code elements:
  - ▶ Classes

## DEFAULT (PACKAGE PRIVATE) ACCESS MODIFIER: SUMMARY

- ▶ When element is declared as **package private**, then only code **inside the same class** or **within the same package** can **access** it
- ▶ **Declarable** code elements:
  - ▶ Fields (variables)
  - ▶ Methods
  - ▶ Constructors
  - ▶ Classes

## PUBLIC ACCESS MODIFIER: SUMMARY

- ▶ When element is declared as **public**, then all code **regardless of location** can **access** it
- ▶ **Declarable** code elements:
  - ▶ Fields (variables)
  - ▶ Methods
  - ▶ Constructors
  - ▶ Classes

## BASIC COUNTER: REQUIREMENTS

### ▶ State

1. Current counter value **cannot** be accessed directly

### ▶ Behaviour

2. Can **increment**, **decrement** and **clear** counter value
3. Can **set** counter value to any specified positive number (otherwise set to 0)
4. Can be constructed only **within** the same package

# 1. BASIC COUNTER: NO DIRECT ACCESS TO STATE

Hide internal state of counter  
by marking it as private

```
public class BasicCounter {
```

```
    private int counter;
```

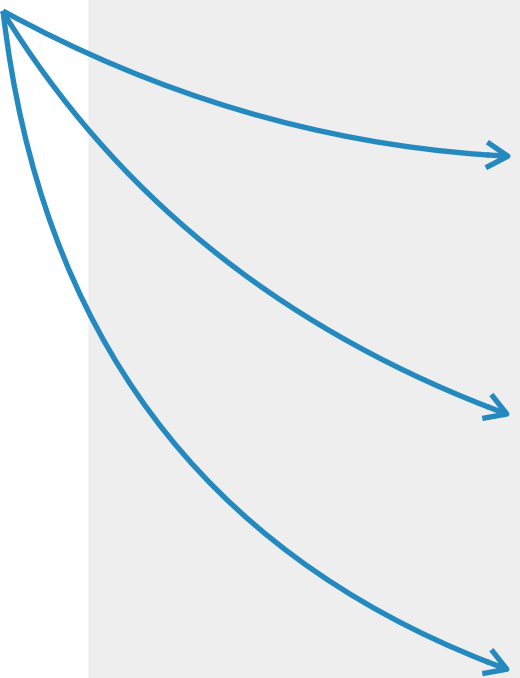

```
    public int getCounter() {  
        return counter;  
    }
```

Allow external access  
by providing getter method }

## 2. BASIC COUNTER: PRIMARY BEHAVIOUR

Control counter from outside  
without direct access to its state

```
public class BasicCounter {  
    ...  
    public void increment() {  
        counter++;  
    }  
    public void decrement() {  
        counter--;  
    }  
    public void clear() {  
        counter = 0;  
    }  
}
```

Three blue arrows originate from the text 'Control counter from outside without direct access to its state' and point to the 'increment()', 'decrement()', and 'clear()' methods of the BasicCounter class, illustrating that the counter's state is managed through these public methods.

### 3. BASIC COUNTER: SECONDARY BEHAVIOUR

Only counter knows  
about validation rules

```
public class BasicCounter {  
  
    ...  
  
    public void setCounter(int counter) {  
        if (isPositive(counter)) {  
            this.counter = counter;  
        } else {  
            clear();  
        }  
    }  
  
    private boolean isPositive(int value) {  
        return value > 0;  
    }  
}
```

## 4. BASIC COUNTER: CONSTRUCTION LIMITATIONS

No access modifier specified  
means it can be called  
within the same package

```
public class BasicCounter {  
    ...  
    BasicCounter() {  
    }  
    ...  
}
```

Empty constructor

## BASIC COUNTER: FINAL RESULT

```
public class BasicCounter {  
    private int counter;  
  
    BasicCounter() {  
    }  
  
    public int getCounter() {  
        return counter;  
    }  
  
    public void setCounter(int counter) {  
        if (isPositive(counter)) {  
            this.counter = counter;  
        } else {  
            clear();  
        }  
    }  
  
    public void increment() {  
        counter++;  
    }  
  
    public void decrement() {  
        counter--;  
    }  
  
    public void clear() {  
        counter = 0;  
    }  
  
    private boolean isPositive(int value) {  
        return value > 0;  
    }  
}
```

# OBJECT EQUALITY AND IDENTITY

## OBJECT AND HEAP MEMORY REVISION

- ▶ When object is **created**, it is being stored in the **heap memory**
- ▶ To be able to **locate** an object, computer assigns it an **address** in the memory
- ▶ **Every new object** created gets a **new address**

# REFERENCE AND OBJECTS IN HEAP MEMORY

## Code view

```
Car car1 = new Car("BMW");  
Car car2 = car1;  
Car car3 = new Car("BMW");
```

## Objects in memory view

## REFERENCE EQUALITY: RELATIONAL OPERATOR

- ▶ Relational operator `==` used to **compare** two operands and determine whether the two operands are **equal or not**
- ▶ When used on **referential type**, we can see if both variables **refer to the same object** in the heap memory

## REFERENCE EQUALITY: CODE EXAMPLE

```
Car car1 = new Car("BMW");  
Car car2 = car1;  
Car car3 = new Car("BMW");  
  
if (car1 == car1) { //true  
}  
  
if (car1 == car2) { //true  
}  
  
if (car1 == car3) { //false  
}
```

## LOGICAL EQUALITY: METHOD EQUALS

- ▶ Every class by default has **equals method** that **compares** object method was called on with specified parameter
- ▶ Compares the **data of the objects** instead of the value of the **references**

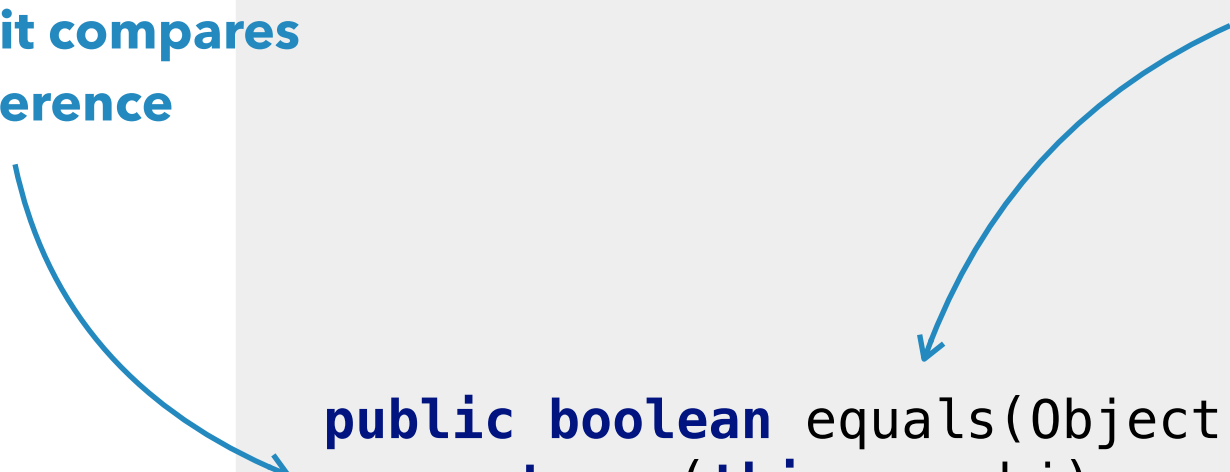

## LOGICAL EQUALITY: CODE EXAMPLE

```
Car car1 = new Car("BMW");  
Car car2 = car1;  
Car car3 = new Car("BMW");  
  
if (car1.equals(car1)) { //true  
}  
  
if (car1.equals(car2)) { //true  
}  
  
if (car1.equals(car3)) { //false  
}
```

# SAME, BUT DIFFERENT, BUT STILL THE SAME

By default it compares  
by reference

Object class default  
equals method implementation

```
public boolean equals(Object obj) {  
    return (this == obj);  
}
```

## OVERRIDE DEFAULT BEHAVIOUR WITH CUSTOM LOGIC

- ▶ **Default** method implementation knows **nothing** about concrete class data, hence reference comparison by default
- ▶ **Control** what **data of the class** should be **compared** and how it should be done

## OVERRIDE DEFAULT BEHAVIOUR: CODE EXAMPLE

```
public class Car {  
    private String brand;  
  
    ...  
  
    @Override  
    public boolean equals(Object o) {  
        if (this == o) return true;  
        if (o == null || getClass() != o.getClass()) return false;  
        Car car = (Car) o;  
        return Objects.equals(brand, car.brand);  
    }  
  
    ...  
}
```

Check argument is not null and both are instances of the same class

Check if both reference the same object

Cast argument to the Car type

Specify which class fields to compare

## LOGICAL EQUALITY AFTER EQUALS OVERRIDE: CODE EXAMPLE

```
Car car1 = new Car("BMW");  
Car car2 = car1;  
Car car3 = new Car("BMW");  
  
if (car1.equals(car1)) { //true  
}  
  
if (car1.equals(car2)) { //true  
}  
  
if (car1.equals(car3)) { //true  
}
```

## TRICKY QUESTION: STRING INSTANTIATION

Instantiating String object  
without new keyword

String artist = "Justin Bieber";

String band = new String("Nickelback");

Instantiating String object  
with new keyword

# EQUALITY DIFFERENCE

## Reference equality

```
String s1 = "Cat";  
String s2 = "Cat";  
String s3 = new String("Cat");  
  
if (s1 == s2) { //true  
}  
  
if (s1 == s3) { //false  
}
```

## Logical equality

```
String s1 = "Cat";  
String s2 = "Cat";  
String s3 = new String("Cat");  
  
if (s1.equals(s2)) { //true  
}  
  
if (s1.equals(s3)) { //true  
}
```

# OBJECT TEXTUAL REPRESENTATION

## WRITING OBJECT DETAILS IN THE CONSOLE: LONG WAY

### Code

```
SmartPhone phone = new SmartPhone("Apple", "iPhone X");  
  
System.out.println("Brand: " + phone.getBrand());  
System.out.println("Model: " + phone.getModel());
```

### Console output

```
Brand: Apple  
Model: iPhone X
```

Process finished with exit code 0

## WRITING OBJECT DETAILS IN THE CONSOLE: FAST WAY

### Code

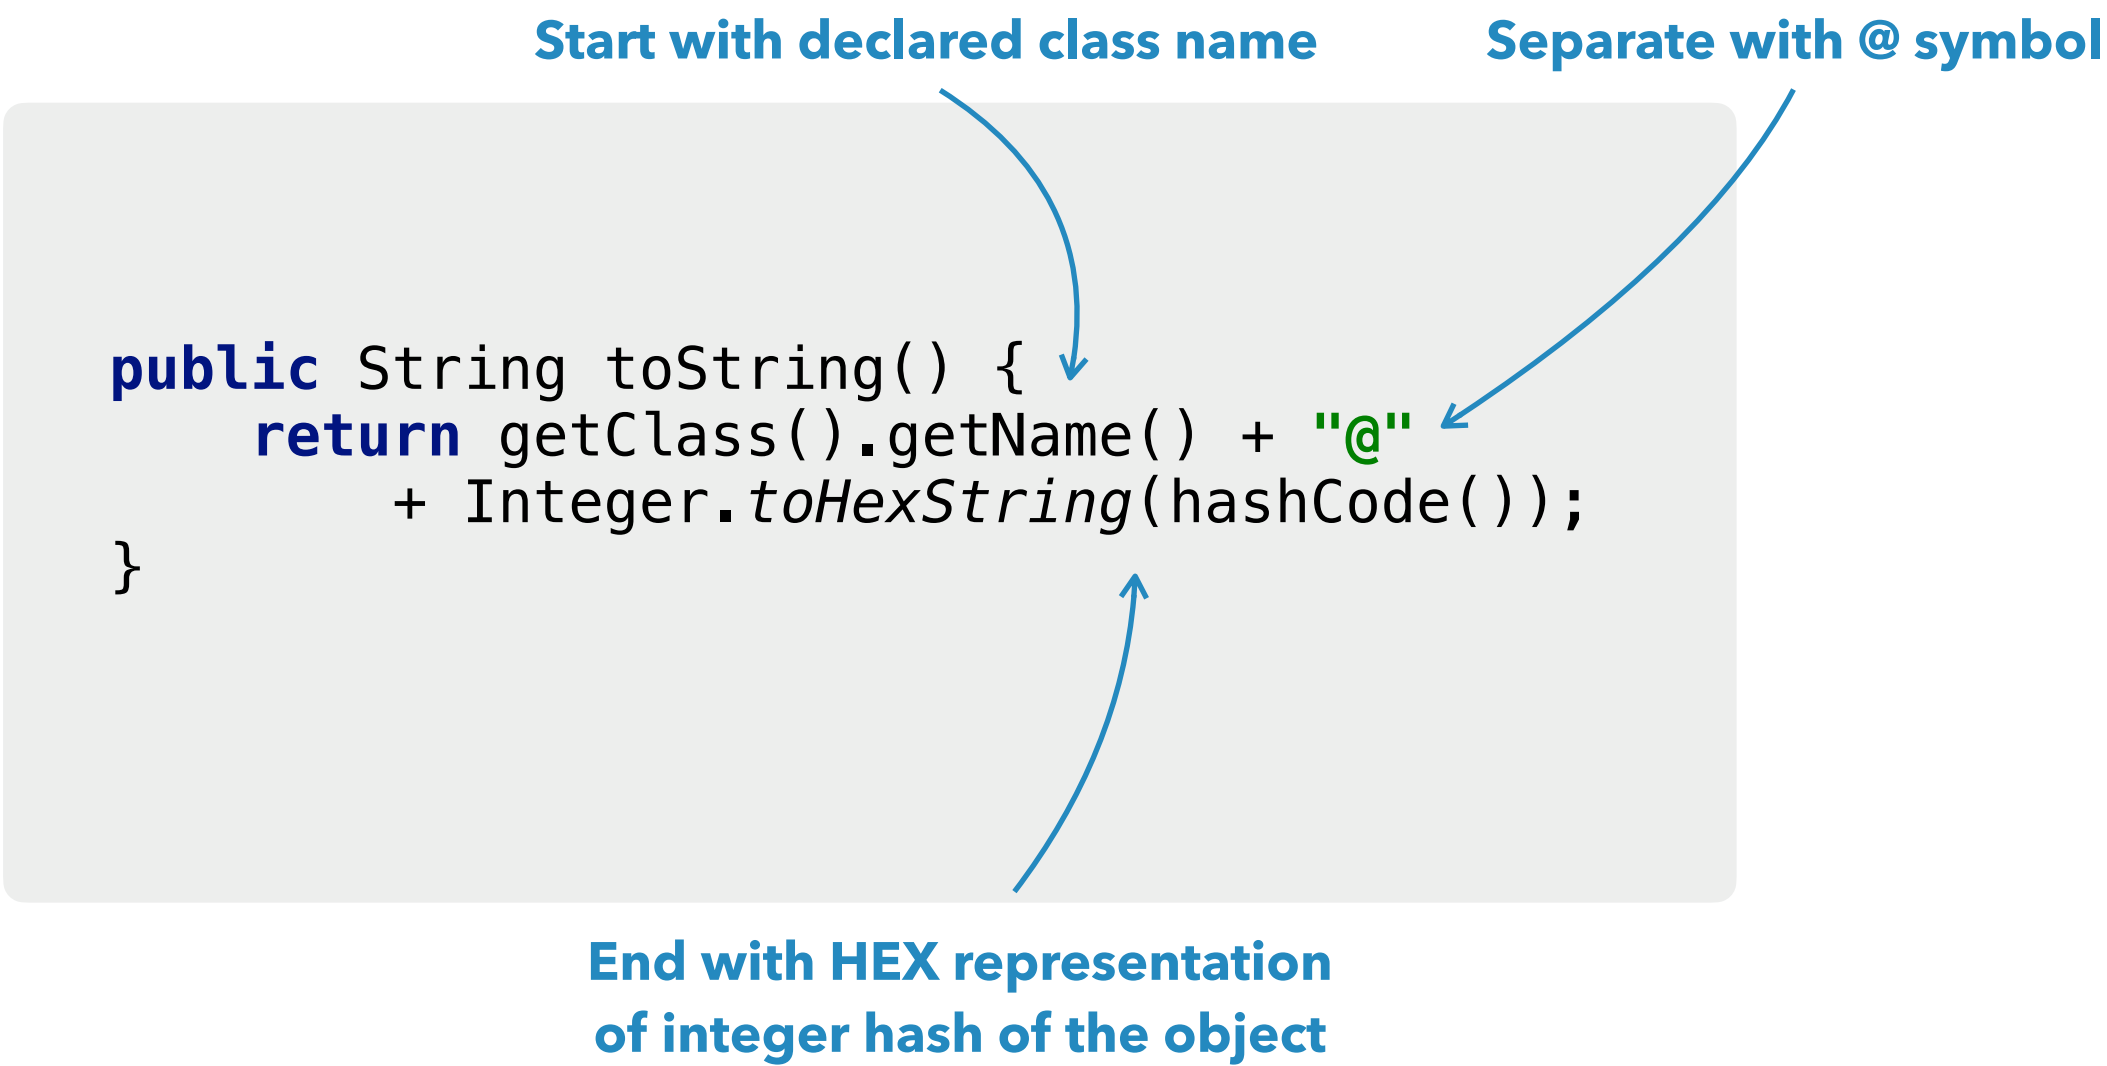

```
SmartPhone phone = new SmartPhone("Apple", "iPhone X");  
System.out.println(phone);
```

### Console output

```
lv.javaguru.lessons.l5.SmartPhone@1540e19d
```

```
Process finished with exit code 0
```

## DEFAULT TO STRING METHOD BEHAVIOUR

```
public String toString() {  
    return getClass().getName() + "@"  
        + Integer.toHexString(hashCode());  
}
```

The diagram illustrates the default `toString()` method implementation in Java. It features a light gray rectangular box containing the code. Three blue annotations with arrows point to specific parts of the code: 'Start with declared class name' points to `getClass().getName()`, 'Separate with @ symbol' points to the `@` character, and 'End with HEX representation of integer hash of the object' points to `Integer.toHexString(hashCode())`.

Start with declared class name

Separate with @ symbol

End with HEX representation  
of integer hash of the object

## OVERRIDE DEFAULT BEHAVIOUR: CODE EXAMPLE

```
public class SmartPhone {  
  
    private String brand;  
    private String model;  
  
    ...  
  
    @Override  
    public String toString() {  
        return "SmartPhone{" +  
            "brand='" + brand + '\\'' +  
            ", model='" + model + '\\'' +  
            "}'";  
    }  
}
```

## WRITING OBJECT DETAILS AFTER OVERRIDE

### Code

```
SmartPhone phone = new SmartPhone("Apple", "iPhone X");  
System.out.println(phone);
```

### Console output

```
SmartPhone{brand='Apple', model='iPhone X'}
```

```
Process finished with exit code 0
```
